# 1 EQ1 - LoRa SF calculation

#### 1.1. Data

In this chapter we answer to question EQ1, asking to find the biggest LoRa SF for having a success rate of at least 70% in a LoRaWAN Network with the following parameters:

- Carrier frequency: CF = 868MHz
- Bandwidth: BW = 125kHz
- Number of gateways:  $N_G = 1$
- Number of sensor nodes:  $N_S = 50$
- Intensity of Poisson process:  $\lambda = 1$  packet/minute
- Success rate:  $SR \ge 0.7$

We compute the payload size based on the last two digits of the leader's person code (XY), according to the formula:

$$L = 3 + XY \text{ Bytes} \tag{1.1}$$

Our leader's person code is 10773593, so the payload size is:

$$L = 3 + 93 = 96$$
 Bytes (1.2)

### 1.2. Maximum Spreading Factor calculation

Since LoRaWAN uses an ALOHA-like procedure to handle channel access and retransmissions, we compute the success rate, SR, as the ALOHA success rate:

$$SR = S/G = e^{-2G} = e^{-2N\lambda t}$$
 (1.3)

Thanks to this formula, we can compute the maximum airtime to have a success rate greater than 70%.

$$SR \ge 0.7\tag{1.4}$$

$$e^{-2N\lambda t} \ge 0.7\tag{1.5}$$

By applying the natural logarithm, we get:

$$-2N\lambda t \ge \ln(0.7) \tag{1.6}$$

$$t \le \frac{-ln(0.7)}{2N\lambda} = \frac{-ln(0.7)}{2 \cdot 50 \cdot \frac{1}{60 \cdot 10^3 \text{ ms}}} = 214.005 \text{ ms}$$
 (1.7)

We now use the API https://www.thethingsnetwork.org/airtime-calculator to find the highest SF that guarantees an airtime smaller than the value we found. We use payload size of 96 Bytes, as computed before, region EU868 and bandwidth 125 kHz. The API says that the maximum payload size for EU868 with SF from 10 to 12 is 51 Bytes; this means that we can evaluate SF values starting from 9 and lowering the SF until we find an airtime smaller than 214.005 ms. The values of airtime corresponding to the SF are report in the following table.

| Spreading Factor | Airtime             |
|------------------|---------------------|
| SF9              | $594.9~\mathrm{ms}$ |
| SF8              | $328.2~\mathrm{ms}$ |
| SF7              | $184.6~\mathrm{ms}$ |

Table 1.1: Airtime based on SF

The only value of SF that leads to an airtime smaller than 214.005 ms and a success rate greater than 70% is SF7.

# 2 | EQ3 - Use LoRaSim to replicate simulations

In this chapter we use the paper âĂIJDo LoRa Low-Power Wide-Area Networks Scale?âĂİ by M. Bor et al. and the LoRa simulator LoRaSim to reproduce the figures reporting the results of two Experiments Sets from the paper. LoRaSim is a simulator based on SimPy for simulating collisions in LoRa networks and consists in four Python scripts simulating different types of network, that can be run setting some parameters. In order to replicate the two figures, we need to understand which transmitter configuration was user for every configuration SN<sup>i</sup> and use the correct simulator with the correct parameters.

### 2.1. Figure 5: Experiment Set 2

The Experiment Set 2 evaluates the impact of dynamic communication parameter selection on the Data Extraction Rate (DER) and compares three transmitter configurations, called SN<sup>3</sup>, SN<sup>4</sup> and SN<sup>5</sup> in the paper.

First of all, we need to choose the correct Python script in the simulator; the paper says that nodes transmit to a single sink (M=1), so we choose the script loraDir.py. From the LoRaSim documentation, we check the parameters used from the selected script, that are reported here:

- ./loraDir.py <NODES> <AVGSEND> <EXPERIMENT> <SIMTIME> [COLLISION] For all experiments, we choose:
  - The number of nodes, <NODES>, is chosen from a list built based on the data point of Figure 5 from the paper.
  - The average sending interval in milliseconds, <AVGSEND>, is set to 1 million of milliseconds, i.e. 16.7 minutes.
  - The simulation time, <SIMTIME>, is not specified from the paper; we choose a simulation time of 58 days, the same as the one used in Experiment Set 1.

• We set <COLLISION> to 1 to enable the full collision check.

The key difference between the different configurations is represented by the  $\langle EXPERIMENT \rangle$  parameter that determines with which radio settings the simulation is run. We are going to choose the experiment looking at how the Experiment Set is described and at the LoRaSim documentation. The paper says that  $SN^3$  uses the settings used by common LoRaWAN deployments, which refers to  $\langle EXPERIMENT \rangle = 4$ .  $SN^4$ , instead, is the configuration that minimizes the airtime for each node, by setting the BW, SF and CR, with constant TP; this description corresponds to  $\langle EXPERIMENT \rangle = 3$ . Finally,  $SN^5$  minimizes first airtime and then Transmission Power, as done by the simulator with  $\langle EXPERIMENT \rangle = 5$ .

The complete code used to simulate the network with LoRaSim and plot the DER is reported here.

```
import os
import subprocess
import math
import pandas as pd
import matplotlib
import matplotlib.pyplot as plt
def simulate(n_nodes, tx_rate, exp, duration):
    env = os.environ.copy()
    env["MPLBACKEND"] = "Agg"
    # Use subprocess.run to execute the command and capture output
    result = subprocess.run(
            "python2",
            "lorasim/loraDir.py",
            str(int(n_nodes)),
            str(int(tx_rate)),
            str(int(exp)),
            str(int(duration)),
            str(int(1))
        ],
        env=env,
        capture_output=True,
        text=True, # Capture output as text
    )
# Der in aloha defined as S/G = e^{(-2G)}
def aloha_der(n_nodes,t):
   rate = 1e-6
```

```
return math.exp(-2 * n_nodes * rate * t)
def main():
   duration = 58 * 86400000
   tx_rate = 1e6
   for n_nodes in list(range(1,10)) + list(range(10,100,10)) + list(
                                        range(100,1000,100)) + list(
                                        range(1000,1601,200)):
        print(f"Simulating {n_nodes} nodes")
        simulate(n_nodes, tx_rate, 4, duration)
        simulate(n_nodes, tx_rate, 3, duration)
        simulate(n_nodes, tx_rate, 5, duration)
   data_sn3 = pd.read_csv("exp4.dat", sep=" ")
    data_sn4 = pd.read_csv("exp3.dat", sep=" ")
   data_sn5 = pd.read_csv("exp5.dat", sep=" ")
    data_sn3["der"] = (data_sn3["nrTransmissions"] - data_sn3["
                                        nrCollisions"]) / data_sn3["
                                        nrTransmissions"]
   data_sn4["der"] = (data_sn4["nrTransmissions"] - data_sn4["
                                        nrCollisions"]) / data_sn4["
                                        nrTransmissions"]
    data_sn5["der"] = (data_sn5["nrTransmissions"] - data_sn5["
                                        nrCollisions"]) / data_sn5["
                                        nrTransmissions"]
   plt.plot(data_sn3["#nrNodes"], data_sn3["der"], marker = 'o', label=
                                        "SN3")
   plt.plot(data_sn4["#nrNodes"], data_sn4["der"], marker = 'o', label=
                                         "SN4")
   plt.plot(data_sn5["#nrNodes"], data_sn5["der"], marker = 'o', label=
                                        "SN5")
   plt.title("Success Rate (%)")
   plt.xlabel("Number of nodes")
   plt.ylabel("Rate")
   plt.legend()
   plt.grid()
   plt.savefig("figure5.pdf")
   plt.show()
if __name__ == '__main__':
   main()
```

The plot that corresponds to Figure 5 from the paper is reported here.
